# Problem 1

### A

#### Version 1

```
#' Version 1: Implement this game using a loop
#'
#' @param n The number of dice to roll.
#' @return Total winnings

v1 <- function(n) {
   tot_win <- 0
   for (i in 1:n) {
      rollnumb <- sample(1:6, 1)
      if (rollnumb %in% 3 | rollnumb %in% 5) {
        tot_win <- tot_win + 2 * rollnumb - 2
      } else {
        tot_win <- tot_win - 2
      }
    }
   return(tot_win)
}</pre>
```

### Version 2

```
#' Version 2: Implement this game using built-in R vectorized functions.
#'
#' @param n The number of dice to roll.
#' @return Total winnings
```

```
v2 <- function(n) {
  rollnumb <- sample(1:6, n,replace = T)
  win=ifelse(rollnumb %in% c(3,5),2*rollnumb-2,-2)
  total_win=sum(win)
  return(total_win)
}</pre>
```

#### Version 3

```
#' Version 3: Implement this by rolling all the dice into one
#' and collapsing the die rolls into a single table()
#'
#' @param n The number of dice to roll.
#' @return Total winnings

v3 <- function(n) {
    rollnumb <- sample(1:6, n, replace = TRUE)
    rollnumb_table <- table(factor(rollnumb, levels = 1:6))

    tot_win <- sum((rollnumb_table[3] * (3*2 - 2)) + (rollnumb_table[5]* (5*2 - 2)), na.rm = TRUE)
    tot_lose <- sum(rollnumb_table[c(1,2,4,6)] * (-2), na.rm = TRUE)

    return(tot_win + tot_lose)
}</pre>
```

### Version 4

```
#' Version 4: Implement this game by using one of the "apply" functions.
#'
#' @param n The number of dice to roll.
#' @return Total winnings

v4 <- function(n) {
    rollnumb <- sample(1:6, n, replace = TRUE)
    winorlose <- sapply(rollnumb, function(x) {
        if (x %in% 3 | x %in% 5) {
            return(2*x-2)
        } else {
            return(-2)
        }
    }
    return(sum(winorlose))
}</pre>
```

```

Comparing the performance with low input of 1000, Version 2 function where we implemented the game using built-in R vectorized functions has the fastest performance. Comparing the performance with high input of 100000, Version 3 function where we Implemented the dice rolls into a single table() has the fastest performance. While version 3 is the fastest, version 2 function performance is similar. In both comparison, Version 1 function where we implemented the game using loop performs the slowest.

#### $\mathbf{E}$

```
# Evidence based upon a Monte Carlo simulation
simnumb <- 1000000
set.seed(123)

# Generate total winnings using version 2 function
total_net_result = v2(simnumb)

# Calculate average net result per game
average_net_result <- total_net_result / simnumb
average_net_result

## [1] 0.666316</pre>
```

```
## [1] 0.6666667
```

1/6\*4+1/6\*8+4/6\*(-2)

Based on the monte carlo simulation, we can see that we win 0.66. Therefore, we can conclude that this is a fair game since we are not loosing anything at least.

# Calculating using probability (just another way of providing evidence)

# Problem 2

```
# Importing the dataset
cars=read.csv("cars.csv")
```

# $\mathbf{A}$

## $\mathbf{B}$

```
# Restrict the data to cars whose Fuel Type is "Gasoline".
cars=cars[cars$FuelType %in% "Gasoline",]
```

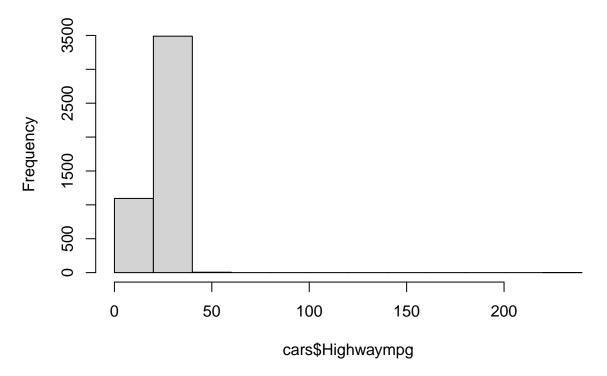

# $\mathbf{C}$

```
# Checking highway mileage variable distribution
summary(cars$Highwaympg)

## Min. 1st Qu. Median Mean 3rd Qu. Max.
## 13.00 21.00 25.00 24.97 28.00 223.00

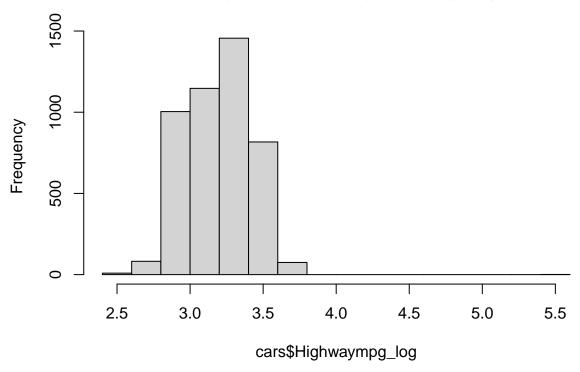

hist(cars$Highwaympg)
```

# Histogram of cars\$Highwaympg

# Log transformation of highway mpg variable
cars\$Highwaympg\_log=log(cars\$Highwaympg)
hist(cars\$Highwaympg\_log)

Highway gas mileage variable is slightly skewed. Although it is not extremely skewed, a log transformation could be used to normalize the highway mpg variable.

## D

```
